

GPT vs. Claude – Coding Task Comparison

Coding Task

For the comparison, I used a simple hospitality-related coding task: **creating a Python program to calculate a hotel guest's total bill, including room charges and tax.**

The purpose was to see how both GPT and Claude handle the same coding requirement and compare their responses based on clarity, correctness, explanation, and ease of use.

GPT Response

GPT provided a straightforward Python solution with clear variables and calculations. The code was easy to understand and could be modified easily if additional charges, discounts, or services needed to be added.

The explanation was also simple enough for someone with basic Python knowledge to understand the logic behind the code.

Claude Response

Claude also provided a working Python solution for the same task. Its response was well-structured and explained the calculation process clearly. The code was readable and could be extended for more hotel billing features.

Comparison

Both GPT and Claude were able to complete the coding task successfully. Their solutions were similar in terms of basic functionality, but there were some differences in how they explained the code and structured the response.

Criteria	GPT	Claude
Code correctness	Good	Good
Code readability	Very clear	Very clear
Explanation	Simple and easy to follow	Detailed and clear
Ease of modification	Easy	Easy

Overall experience	User-friendly	Well-structured
--------------------	---------------	-----------------

Conclusion

From this comparison, I found that both GPT and Claude are useful for coding-related tasks. For a simple hospitality application, either model can help generate and explain code. The final choice can depend on the type of task, the required level of explanation, and the user's preference.

Data-Privacy Checklist for Using Third-Party LLMs with Guest PII

When using third-party Large Language Models (LLMs) in a hospitality environment, guest information needs to be handled carefully. Hotels may work with sensitive information such as guest names, phone numbers, email addresses, booking details, identification information, and payment-related data.

The following checklist can help reduce privacy risks:

1. Minimize Guest Data

Only provide the information that is actually required for the AI task. Avoid sending complete guest records when a smaller amount of information is enough.

2. Mask Personal Information

Where possible, remove or replace details such as guest names, phone numbers, email addresses, booking IDs, and other identifying information before sending data to an external LLM.

3. Check the LLM Provider's Privacy Policy

Before using a third-party LLM, understand how the provider handles submitted data, including whether the data is stored, used for training, or shared with other services.

4. Protect Data During Transfer

Guest information should be securely transmitted using appropriate encryption and secure connections. Sensitive information should never be sent through insecure channels.

5. Control Access

Only authorized employees or applications should be allowed to access guest information and AI systems that process it.

6. Avoid Sending Highly Sensitive Information

Payment card details, passwords, identity-document information, and other highly sensitive data should not be sent to an LLM unless there is a clear, approved business and security process for doing so.

7. Follow Company Policies

AI usage should follow the organization's data-protection, security, and compliance policies. Employees should know what information they are allowed to enter into external AI tools.

8. Delete Data When No Longer Needed

Guest information should not be kept longer than necessary. Data retention and deletion rules should be clearly defined.

9. Monitor AI Usage

Organizations should regularly review how employees and applications are using third-party LLMs to identify possible privacy or security issues.

10. Keep a Human in the Loop

AI-generated responses involving guest information should be reviewed when necessary, especially when they could affect bookings, payments, complaints, or other important guest decisions.

Overall Conclusion

Using LLMs such as GPT and Claude can be very useful in hospitality for tasks like coding, customer support, booking assistance, and data processing. However, guest privacy should always come first. By minimizing PII, controlling access, protecting data, and following company policies, organizations can make better and safer use of third-party AI tools.
